

QA Testing Report

Rolling Style

Version Tested: v1.0.0.0

Package: org.rollingstyle.twa

Report Date: May 09, 2026

Prepared by: PrimeTestLab QA Team
primetestlab.com

Executive Summary

This report covers QA testing of Rolling Style v1.0.0.0. A total of 7 findings were identified: 2 Critical, 3 Major, and 2 Minor. Two Critical items (SMS authentication and item upload) currently block users from signing in and from listing items, which together prevent the marketplace from functioning. The remaining items are layout, navigation, and feature-completeness issues that can be addressed once sign-in and uploads are working.

Critical Attention Needed

Two Critical issues were found during testing. SMS verification codes are not being delivered (Issue #4), so users cannot sign in at all, and item uploads fail with a connection error (Issue #5), so sellers cannot list anything. These two together block the core marketplace experience and need to be resolved before the closed-testing period closes. The remaining findings cover navigation, layout, and missing features.

Testing Overview

App Name	Rolling Style
Version Tested	v1.0.0.0 (Latest: v1.0.0.0)
Package Name	org.rollingstyle.twa
Test Device	Huawei Honor STK-LX1
Operating System	Android 10
Network	Mobile Data
Testing Period	14-day Closed Testing
Testing Types	Functional, UI/UX, Performance, Policy Compliance
Total Findings	7 (2 Critical, 3 Major, 2 Minor)

Section A — Findings

The findings below are presented in the order they were submitted. Each issue includes a description, expected and actual behavior, a recommendation, and a priority. Issues #2 and #3 share a common root cause around the underlying web view's touch and zoom handling, and Issues #1, #4, and #5 are infrastructure-level (TWA configuration, SMS auth setup, upload backend) that benefit from being audited together. Recommendations from the client's suggestions list have been folded directly into the relevant issue recommendations rather than listed separately.

Issue #1: App Opens Website Instead of App — Tapping the icon launches a web page

Severity	Major
Description	When users tap the app icon, the experience opens as a website rather than as a native or app-style interface. The package suffix indicates this build is a Trusted Web Activity (TWA), which wraps a web page in an app shell, but the wrapping is not behaving correctly. Users see what looks like a browser experience instead of an app, which is confusing and reduces trust in the product.
Expected Behavior	Tapping the app icon should open the app inside its own surface, with no visible browser chrome (URL bar, tab indicators, browser menus). The user should feel they are inside an app, not on a website.
Actual Behavior	Tapping the icon redirects users to a web page or shows visible browser elements, breaking the app experience and making the product feel like a shortcut rather than a real app.
Recommendation	Check the TWA configuration in the manifest and the digital asset links setup. Verify that the assetlinks.json file is published and accessible at the website's /.well-known/assetlinks.json path, that the SHA-256 fingerprint matches the signing key used for the Play Store build, and that the package name matches exactly. If the asset links are missing or invalid, Android falls back to opening the URL in a Custom Tab or browser, which produces exactly the behavior described. Re-verifying these three pieces (assetlinks file, fingerprint, package name) usually resolves it.
Priority	High

Issue #2: Small Text and Images in UI — Content requires zoom to read comfortably

Severity	Minor
Description	On the home and product details pages, text and images appear smaller than expected for a mobile interface. Users have to pinch to zoom in order to read product names, prices, and details comfortably, which is inconsistent with how mobile shopping apps usually behave. This is most likely a viewport or scaling issue inherited from the underlying website rather than a per-element styling problem.
Expected Behavior	Text and product images should be sized for comfortable reading and tapping on a mobile screen, with no zoom required. Body text should typically be at least 14 to 16 pixels and product images should fill a meaningful portion of the screen.
Actual Behavior	Text appears small and dense, and product images are smaller than expected, forcing users to zoom in to see what they are looking at.
Recommendation	In the underlying web app, ensure the viewport meta tag is set to width=device-width and initial-scale=1, and review the base font size and image sizing on the home and product pages. Use responsive units (rem, em, or viewport units) so content scales with screen size. Larger product images and at least 14 to 16 pixel base text will make the app feel native to mobile and remove the need for zooming.
Priority	Medium

Issue #3: Home Category Tap Issue and Accidental Zoom — Categories
require multiple taps and sometimes zoom instead

Severity	Major
Description	On the home page, tapping a category (such as shoes or clothes) does not reliably open the category. Users often need to tap multiple times before the category opens, and in some cases the screen zooms in instead of navigating. This breaks the primary discovery flow on the home page and is closely related to Issue #2, since both stem from how the underlying web view handles touch input and zoom.
Expected Behavior	A single tap on a category should open that category's listing immediately. Tapping should never trigger a zoom action.
Actual Behavior	Single taps frequently fail. Users have to tap two or three times to navigate, and occasionally the screen zooms instead of opening the category, leaving the user on a zoomed-in home page.
Recommendation	Disable user scaling in the viewport meta tag (user-scalable=no, or maximum-scale=1.0) so accidental double-taps do not trigger zoom. On the category elements, add touch-action: manipulation in CSS to remove the 300 ms tap delay and prevent the browser from interpreting taps as zoom gestures. Combined with the font and image sizing fix in Issue #2, this will make the home page feel responsive and predictable on a single tap.
Priority	High

Issue #4: SMS Code Not Received During Login — Phone authentication completely broken

Severity	Critical
Description	When users enter their phone number on the login page and request an SMS verification code, no code is delivered. Because phone-number SMS appears to be the primary authentication method in the app, this means users cannot sign in at all. New users cannot create accounts, and returning users cannot log back in. This blocks every feature that requires an account, including uploading items, viewing order history, and managing a profile. As a Play Store submission, an unusable login flow will also block closed-testing approval.
Expected Behavior	After entering a valid phone number and tapping the request button, users should receive an SMS verification code within a few seconds. Entering that code should complete sign-in successfully.
Actual Behavior	No SMS is delivered at all. The user is left waiting on the verification screen with no code arriving and no clear error message about why.
Recommendation	Audit the SMS authentication setup end to end. If using Firebase Phone Auth, confirm that the SHA-256 fingerprint of the production signing key is registered in the Firebase project settings, that the Phone provider is enabled in the Authentication section, and that the project has SMS quota or billing enabled (Firebase Phone Auth requires the Blaze plan beyond a low free tier). If using a third-party SMS provider, verify the API key, sender ID, and that the destination country is allowed. Also check the app's network and permission configuration so the verification request actually reaches the auth backend. This should be the first item fixed because nothing else in the app is reachable until users can sign in.
Priority	High

Issue #5: Cannot Upload Clothing Items (Connection Error) — Item publish fails with "not connected" error

Severity	Critical
Description	When users fill in clothing details (price, size, image, and other fields) and tap publish or send, the upload fails with a "not connected" error message. Because uploading items is the core function of the marketplace (sellers cannot list anything without it), this issue effectively breaks the primary value of the app. Even if other parts of the app work, sellers have no way to contribute inventory.
Expected Behavior	After filling in valid clothing details and tapping publish, the item should upload to the marketplace and appear in the user's listings, with a clear success confirmation.
Actual Behavior	The publish action fails with a "not connected" error, regardless of the device's actual network state, suggesting the upload endpoint or the backend connection itself is misconfigured rather than a real network outage.
Recommendation	Check the upload endpoint URL and authentication on the backend, including any required headers (auth token, content-type, multipart boundary for image uploads). Confirm CORS settings on the API allow requests from the TWA's origin, and verify that file size limits on the server are not silently rejecting the image. Adding a clearer error message that distinguishes between actual network failures, server errors, and validation errors will also help users (and you, in future testing) understand what went wrong. Like Issue #4, this is a Critical blocker because the marketplace cannot function without working uploads.
Priority	High

Issue #6: Favorites Feature Not Available in Product List — No way to save items for later

Severity	Major
Description	The clothing list does not include any option to add items to favorites. There is no heart icon, bookmark, or save button on product cards or detail pages, so users have no way to mark items they are interested in for later. For a shopping app, the inability to save items meaningfully reduces engagement, since users typically browse first and decide later.
Expected Behavior	Users should be able to mark items as favorites from both the product list and the product detail page, with a clearly visible icon (typically a heart) that toggles the favorite state. Saved items should be accessible from a dedicated Favorites or Wishlist section.
Actual Behavior	No favorites or wishlist control is shown anywhere on product cards or detail pages, so users cannot save items at all.
Recommendation	Add a heart icon to each product card and to the product detail page, with a tap handler that toggles favorite state for the signed-in user. Persist the favorites list in the user profile on the backend so it stays in sync across sessions and devices. Add a Favorites section accessible from the main navigation or profile so users can revisit saved items easily.
Priority	Medium

Issue #7: Back Button Too Small and Unclear — Easy to miss when navigating back

Severity	Minor
Description	When viewing a clothing item from the home page, the back button used to return to the previous screen is very small and visually unclear. Users may have trouble finding it or hitting it accurately, which makes basic navigation feel awkward, especially on a mobile shopping flow where users frequently move back and forth between lists and details.
Expected Behavior	The back button should be clearly visible and easy to tap, with a minimum tap target of around 44 by 44 pixels and a contrasting color or background so it stands out.
Actual Behavior	The back icon is small and blends into its surroundings, making it hard to notice and easy to miss when tapping.
Recommendation	Increase the back button's size to a comfortable tap target (around 44 by 44 pixels) and improve its visual contrast against the page background, either by using a slightly bolder icon weight, a contrasting color, or a subtle circular background. As an alternative or addition, the device's system back gesture should also work reliably as a fallback, so users have two ways to navigate back.
Priority	Medium

Summary Table

#	Finding	Severity	Priority	Status
1	App Opens Website Instead of App	Major	High	Open
2	Small Text and Images in UI	Minor	Medium	Open
3	Home Category Tap Issue and Accidental Zoom	Major	High	Open
4	SMS Code Not Received During Login	Critical	High	Open
5	Cannot Upload Clothing Items (Connection Error)	Critical	High	Open
6	Favorites Feature Not Available in Product List	Major	Medium	Open
7	Back Button Too Small and Unclear	Minor	Medium	Open

Next Steps

The two Critical items (Issues #4 and #5) are the highest-priority fixes in this report. SMS authentication and item upload together are what make the marketplace usable, so until both are working the rest of the app cannot really be tested by real users. Audit the Firebase or SMS provider configuration first (signing fingerprint, phone provider enabled, billing or quota), then the upload endpoint (URL, auth headers, CORS, file size limits) so both flows recover at once.

Issue #1 (app opens as a website) is most likely a Trusted Web Activity setup problem. Verifying the `assetlinks.json` file is published at the expected path, that the SHA-256 fingerprint matches the production signing key, and that the package name is consistent will usually resolve it. This is a quick check that gives a large quality lift, since it removes the visible browser feel.

Issues #2 (small text and images) and #3 (category tap and accidental zoom) share a root cause in the underlying web view's viewport and touch handling. Setting a proper viewport meta tag, disabling user-scalable zoom, adding touch-action: manipulation on tappable elements, and increasing base font and image sizes will resolve both at once. Treating them together is much faster than addressing them one at a time.

Issue #6 (favorites missing) and Issue #7 (small back button) are independent and can be addressed alongside other planned UI changes. Favorites is a meaningful feature for shopping engagement and is worth implementing soon after the Critical fixes; the back button fix is a small change with a noticeable improvement to navigation comfort.

You don't need to fix everything in this report at once, but the two Critical items need to be addressed before the closed-testing period closes since they currently prevent users from signing in and from listing items. One small update during the 14-day closed testing period is all Google Play requires, and that update should focus on the auth, upload, and TWA configuration first.

Update your app with the changes and let me know. I will retest the app for the new changes and provide an updated report.
